Rows 1–2 compare eq. (20) against a full bootstrap under eq. (2)'s OWN noise model: the formula is right to a factor of about two, so the shortfall is not in the algebra. No κ bar appears: κ approximates eq. (1), the solver does not use it, and placing it beside measured quantities would imply it is one. Applying it would move row 1 to 0.40 on D_{11} — still far below every empirical row, which is the point.
