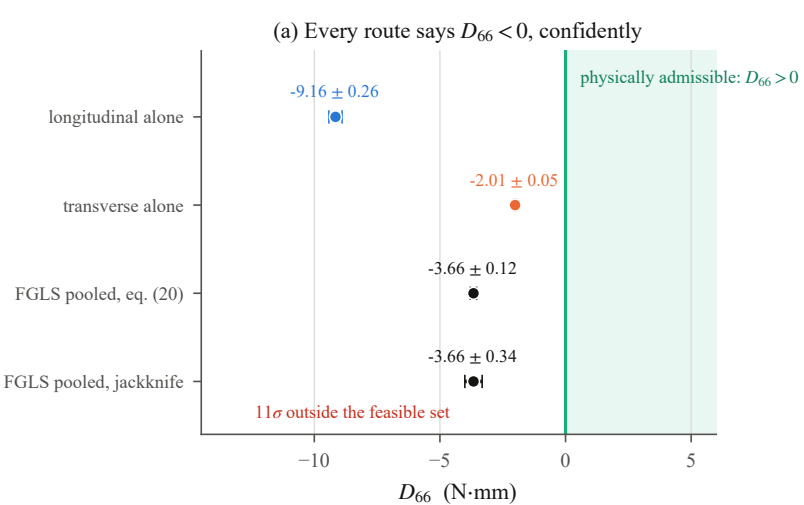
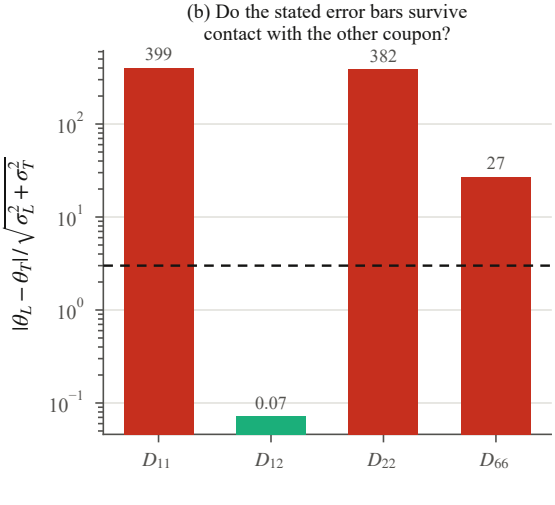
D_{66}: the error bar is small and the answer is still wrong





A variance is a statement about repeatability, not about truth. In (b) every coefficient fails by a wide margin, but for two different reasons: D_{11} and D_{22} because one coupon cannot see them yet still quotes a tight σ, D_{66} because neither coupon can see it and the two nonetheless disagree by 7.1 N·mm — larger than $|D_{66}|$ itself.
